ABSTRAGT

The Test of English as a Foreign Language (TOEFL) was examined for instances in which the item performance of examinees with comparable scores differed according to their native languages. A chi-square procedure, sensitive to deviations of less than ten percent from the expected frequencies of correct item responses across several language groups, revealed significant differences on seven-eighths of the TOEFL items. Reviewers familiar with particular languages could attribute the relative advantage or disadvantage of those language groups on a specific item to linguistic similarities or dissimilarities with the English language. Reviewers could not, however, identify which items would exhibit differential performance across groups based upon inspection of a test form and answer key alone. These findings suggest that examinees' performance on given items in a test of proficiency in a second language will vary according to linguistic contrasts with their native language and that statistical procedures will be necessary for identifying items with exaggerated or unexplained differences across language groups. Four appendices provide a large number of statistical tables and graphs. (Author/AMH)

FL 012 807

The Test of English as a Foreign Language (TOEFL) was developed in 1963 by a National Council on the Testing of English as a Foreign Language, which was formed through the cooperative effort of over thirty organizations, public and private, that were concerned with testing the English proficiency of nonnative speakers of the language applying for admission to institutions in the United States. In 1965, Educational Testing Service (ETS) and the College Board assumed joint responsibility for the program and water 373 a cooperative arrangement for the operation of the program was entered into by ETS, the College Board, and the Graduate Record Examinations Board. The membership of the College Board is composed of schools, colleges, school systems, and educational associations; Graduate Record Examinations Board members are associated with graduate education.

ETS administers the TOEFL program under the general direction of a Policy Council that was established by, and is affiliated with, the sponsoring organizations. Members of the Policy Council represent the College Board and the Graduate Record Examinations Board and such institutions and agencies as graduate schools of business, junior and community colleges, nonprofit educational exchange agencies, and agencies of the United States government.

INTRODUCTION

Whether some test items offer an unfair advantage or disadvantage for particular groups of examinees is a difficult question. Its poses difficulties in detecting those items on which examinees' performance varies by group rather than by overall ability, in determining the extent of the discrepancy in item performance among groups, and in interpreting the reasons for discrepant item performance by groups. The present study addresses these problems within the context of the performance of foreign language groups on the Test of English as a Foreign Language (TOEFL), a test of proficiency in the English language which is taken annually by approximately 250,000 foreign applicants to colleges and universities in the United States. Because discrepant item performance on a test of English proficiency may be related to linguistic similarities and dissimilarities with foreign examinees' native languages, this context would seem to offer an unusual opportunity to tie discrepant item performance to specific features of the group's native language.

There have been several recent studies comparing statistical procedures for detecting item bias (Ironson & Subkoviak, 1979; Rudner, Getson & Knight, 1980a, 1980b; Shepard, Camilli & Averill, 1980). Such procedures include analysis of variance of item difficulty values by groups (e.g., Cleary & Hilton, 1968), plots of item difficulty values by groups (e.g., Angoff & Ford, 1973; Angoff & Sharon, 1974); comparisons of item characteristic curves by groups (e.g., Lord, 1980, and chi-square analysis of item response frequencies by groups (e.g., Scheuneman, 1979).

Each of these techniques has certain strengths and weaknesses in terms of its sensitivity to discrepant item performance, its susceptibility to variation due to irrelevant factors, and its ease of implementation as a routine part of the test development process. No single statistical procedure, however, seems to be fully satisfactory though each may be adequate for a given situation. The chi-square analysis, the statistical procedure chosen for this study, lends itself readily to a context involving several different groups and adapts easily to yield a measure of the extent of discrepant item performance among groups.

Despite the widespread interest in statistical procedures for defecting instances of possible item bias, there has been little attention devoted to developing meaningful indices of the extent to which groups of comparable ability differ with respect to their performance on specific test items. It has perhaps been implicit that the magnitude of statistical tests of significance or the probability level of such significance tests convey sufficient information about an item. And differences certain statistical procedures suggest their own indices: in the difficulty parameter (b) of groups' item characteristic curves (Lord, 1977, 1980) and perpendicular distances to the line of best fit in plots of item difficulty values (Angoff & Sharon, 1974; Sinnott, 1980), for example. Yet differential item performance expressed as a difference in b parameter or as a distance in delta units may fail to convey the extent of a up's relative advantage or disadvantage on a scale familiar to concerned audiences (e.g., test developers, policy makers, group members). Taking simple differences in the percentage of correct item

responses between groups is a misleading altegnative since it assumes equal ability among groups regardless of each group's prior experience, instruction, or other possible dimensions of natural and cultural differences among groups which might affect ability. Stricker (1981) notes limitations of current statistical procedures and proposes the use of a partial correlation coefficient for reflecting the strength of association between item performance and group membership with total test score held constant. But the magnitude of this index would fluctuate according to the proportions of examinees passing and failing an item and would be insensitive to changes in an item's discrimination power at different levels of ability (Stricker, 1981). The present study involves several foreign language groups and simply extends chi-square analysis to provide. a measure of discrepant item performance by comparing the øbserved frequency of correct item responses with the expected frequency of correct, item responses by group. The percentage deviation of the observed from the expected frequency of correct item responses describes a group's relative advantage or disadvantage on a scale that seems inherently meaningful.

Even with an appropriate statistical procedure for detecting discrepant item performance and some measure for determining the extent of a group's relative advantage or disadvantage, it is still often difficult to identify the reasons for the group differences found.

Scheuneman (in press) reminds us that early studies of item bias probably began with the assumption that the reasons for differential item performance would be self-evident once items had been earmarked by statistical procedures. But such revelations following closer scrutiny of item

suggests that statistical procedures simply identify items on which there is differential performance by groups, not necessarily items on which there exist clear contextual cues or any other evident explanation for observed discrepancies in group performance. Whether statistical or contextual evidence is alone sufficient to demonstrate item bias seems a moot point. On a test of English proficiency there should certainly be discrepant item performance across foreign language groups that have different degrees of affinity to the English language. This study examined procedures for uncovering instances of discrepant item performance using both statistical and judgmental approaches.

The study thus had three primary objectives: (a) to detect instances of differential item performance across foreign language groups on the TOEFL through the use of an appropriate statistical procedure; (b) to express each group's relative advantage or deladvantage on TOEFL items on a meaningful scale; and (c) to examine the linguistic features of discrepant items for possible generalities applicable in subsequent test development. This follows and extends the earlier research of Angoff and Sharon (1974) which dealt with differential item performance on the TOEFL through analysis of variance and plots of item difficulty values.

METHOD

Samples of test candidates representing six different foreign language groups were drawn from two international administrations of the TOEFL. A chi-square analysis by language group, correct-incorrect item response, and score level was performed for each of the three distinct TOEFL sections for each test administration. Specialists in English as a foreign

language reviewed the results from the first test administration regarding discrepant item performance and language groups percentage deviations from expected frequencies of correct item responses, and then attempted to identify probable instances of discrepant item performance on a second test form from a judgmental rather than statistical perspective based on their reviews and expertise.

Samples \

The language groups included test candidates whose native languages were: African; Arabic; Chinese; Germanic; Japanese; and Spanish. The latter five native languages were also in the study of item-group interactions by Angoff and Sharon (1974) and all six anguages were in the recent study of the test's factor structure by Swinton and Powers (1980). These particular language groups had been chosen both for their diversity and for their volume of test candidates. Arabic, Chinese, and Japanese represent language groups with high numbers of TOEFL candidates. Germanic and Spanish represent language groups with strong linguistic similarities to the English language. The African language groups.

Samples of approximately 1,000 test candidates from each language group were drawn from data files for two international TOEFL administrations given in November 1976 (Form YTF4) and November 1979 (Form BTF11). The analysis of two test forms provided a check on the stability of findings for discrepant item performance by forms. Similarly, for both administrations, a second sample of Chinese candidates was drawn in order to permit the checking of results for fluctuations which might arise from sampling alone. The African samples actually included four languages in the

Guinea-Senagalese region (i.e., Ibo, Yoruba, Efik, and Fanti) and the Germanic samples included a number of related native languages (i.e., German, Dutch, Swedish, and Danish) so that minimum sample size would be close to 500 with all test candidates from these groups.

Data Analysis

The chi-square analysis performed, in this study was a modification of the procedure described by Scheuneman (1979). Scheuneman's statistic is a direct function of the proportion of correct item responses (Scheuneman, 1979, 1981) and does not have a null distribution that follows a chasquare statistic for large samples (e.g., Baker, 1981; Shepard et al., 1980). The frequency of both correct and incorrect item responses should enter into calculation of the appropriate chi-square statistic.

Detecting discrepant item performance necessarily involves an analysis of item responses by groups. Groups may differ in the relevant ability and examinees at different levels of ability should exhibit different frequencies of correct item responses. Clearly then statistical procedures for detecting discrepant item performance must take ability level into consideration. In our chi-square analysis this is accomplished by contrasting the observed and expected frequencies of item responses across groups within score strata. The distribution of scores is broken down into a reasonable number of strata, where a larger number of strata offer greater control for overall group differences in ability under the assumption that the scores indeed represent a valid measure of the same construct across groups.

The total chi-square value calculated for each item in this study

took the form:

$$\chi_{\alpha}^{2} = \begin{cases} \sum \sum \\ i \neq k \end{cases} \cdot \left(\frac{n_{ijk} - \frac{n_{ij+} \times n_{i+k}}{n_{i+k}}}{\left(\frac{n_{ij+} \times n_{i+k}}{n_{i+k}} \right)^{2}} \right)$$

where

- α refers to a specific item within each test section of the three exparate TOEFL Sections on Listening Comprehension ($\alpha = 1, 2, ..., 50$), Structure and Written Expression ($\alpha = 1, 2, ..., 40$), and Reading Comprehension and Vocabulary ($\alpha = 1, 2, ..., 60$);
- i refers to a given score stratum for a test section, with approximately equal percentages of test candidates within each stratum (i = 1,2,...,10);
- j refers to a particular group, here six different foreign
 language groups as well as a duplicate sample for one
 group (j = 1,2,...,7);
- k refers to a particular item response, here correct or incorrect (k'= 0 incorrect, 1 correct);
- nijk is the frequency of test candidates within the ith score stratum from the jth language group with response k;
- n_{ij+} is the rotal frequency of test candidates within the ith score stratum from the jth language group, regardless of item response;
- score stratum with item response k, regardless of language groups; and

-8-

n i++ is the total frequency of test candidates within the ith score stratum, regardless of language group or item response.

It should be clear that n_{ijk} is simply an observed cell frequency in a three-way classification table of item responses, language groups, and score strata. Similarly, n_{ij+} , n_{i+k} , and n_{i++} represent marginal totals of these cell frequencies in the same three-way classification table. The degrees of freedom for each χ^2_{α} would be equal to S(L-1)(C-1), where \$ represents the total number of score strata, L the total number of groups, and C the total number of possible item responses. This approach also permits checking for discrepant item performance at a particular score stratum by omitting the summation over strata and examining each of the S_i values for χ^2_{α} (i) as a chi-square statistic with (L-1)(C-1) degrees of freedom.

While n_{ijk} denotes the observed frequency of item performance by language group and score stratum, the subtrahend of the numerator and the denominator in the equation for χ^2_{α} denote the expected frequency of item performance for the same language group and score stratum:

$$\hat{n}_{ijk} = \frac{n_{ij+} \times n_{i+k}}{n_{i++}}$$

$$= n_{ij+} \times \frac{n_{i+k}}{n_{i++}}$$

The first term, n_{ij+} , is the total number of test candidates from a particular language group, L_i , within a given score stratum, S_i ; the second term, $\frac{n_{i+k}}{n_{i+l}}$, is independent of language groups and represents the proportion of test candidates in the total sample from that same score stratum with item response k. The product of these two terms must then be

the expected frequency of item performance for a single cell in the three-way classification table.

Denoting correct item responses by the substitution of the subscript 1 for k, the observed and expected frequencies of correct item responses for the ith score stratum, S_i , and jth language group, L_j , can be written as n_{ij1} and \hat{n}_{ij1} . The value for n_{ij1} is an observed frequency and for \hat{n}_{ij1} follows from the equation for \hat{n}_{ijk} . Deviations from expected frequencies of correct item responses for a given L_i become:

$$d_{j1} = n_{+j1} - \hat{n}_{+j1}$$

This is easily expressed as a percentage deviation from the expected frequency of correct item responses for a particular language group, L_j , by collapsing across score strata and dividing by expected frequencies, with multiplication by a constant for conversion into percentages:

$$b_{j1} = \frac{d_{j1}}{\hat{n}_{+j1}} \times 100$$

For correct item responses, b_{j1} reflects the relative advantage or disadvantage for a particular language group in comparison with the total sample as a simple percentage. There is such a percentage deviation from expected frequency of correct item responses for each language on each test item.

These analyses for discrepant item performance, both χ^2_α and b_{jl} , aggregate across score strata and thereby make an implicit assumption regarding the stability of relative advantages and disadvantages across strata. This assumption is equivalent to the assertion that there is no three-way interaction among item response, language group, and score

stratum (i.e., the relative advantage or disadvantage of a group on an item is the same in each score stratum). Likelihood-ratio chi-square values for interaction were computed according to the log-linear models described in Bishop, Fienberg and Holland (1975).

Probabilities of correct item responses within groups were also converted to the delta scale according to an inverse normal transformation (see Angoff & Sharon, 1974). The area of the normal curve, N(13,4), above a given point on this scale corresponds to the probability of a correct response. This transformation facilitates the interpretation of the correlations of item difficulty values between groups. The correlations present another description of the agreement in item difficulties among different groups.

Specialist Reviews

The results of the above analyses from the first test administration were submitted to specialists in English as a second or foreign language for review. These persons were university faculty members who served on committees responsible for research and test development activities for the TOEFL. Their task was to suggest plausible explanations for the discrepant item performance on the ten items within each TOEFL section that had the highest chi-square values. The information made available for the review included the test form and answer key, means and standard deviations of section scores by language groups, item difficulty values by language groups, chi-square values by items, the rank-order of items within sections according to their total chi-square values, and percentage deviations from expected frequencies of correct item responses by language groups (see Appendix D).

After examining these materials and suggesting plausible explanations for discrepant item performance, reviewers turned to a second test form and answer key and, on the basis of their experience with the first form and their expertise in the field, attempted to select the ten items from each section which would in their judgment show the largest relative advantages or disadvantages across the same language groups. The only information made available for this second review was the test form and answer key. Reviewers had to use item content and their knowledge of linguistic similarities and dissimilarities, as well as findings from the first form, in order to identify potential instances of discrepant item performance.

RESULTS · AND DISCUSSION

Language Groups

The samples of test candidates whose native languages were Chinese, Japanese, and Spanish approached 1,000 examinees for each language group on both test administrations. The African, Arabic, and Germanic groups included all examinees with the appropriate native languages for the first test administration. For the second test administration it was possible to sample approximately 1,000 examinees whose native language was Arabic, but the African and Germanic groups again included all examinees from the designated native languages.

These groups differed in other respects besides their native languages.

Naturally there were differences in native country both across and within language groups. Nearly all test candidates in the Japanese group came from Japan and in the African group from Nigeria. The native countries for examinees in the Germanic group (i.e., Germany, Netherlands, Sweden,

and Denmark), closely followed their respective native languages. The Arabic group came primarily from Jordan, Lebanon, and Egypt. The dominant native country for Chinese test candidates was Hong Kong in the first test administration and Taiwan in the second test administration.1 Candidates" reasons for taking the TOEFL varied somewhat by administration as well as by language group; candidates usually cited application to either an undergraduate collège or a graduate school as their reason for taking the test. Only the African language group showed a clear majority (85%) applying to undergraduate colleges in both administrations. Close to ninety percent of the African and Arabic test candidates were males; the other language groups had a less dramatic majority of male test candidates with the highest percentage of female test candidates in the Germanic sample (44%). There were even differences among the language groups in their prior exposure to the TOEFE, with approximately one-fourth of the Arabic, Chinese, and Japanese samples reporting a previous TOEFL administration. Appendix A presents descriptive profiles of the language groups with regard to these characteristics.

Test Performance and Item Difficulties

The test performance of the language groups is reported in Table 1 in terms of the number of correct item responses by test section. The order of the language groups in this table follows their rank-order in total test score. It is apparent that the two language groups with the closest affinity to the English language, Germanic and Spanish, attained the highest test scores. The high mean scores of the African group on Structure

lTaiwanese test candidates had been omitted from the first sample due to the conditions of test administrations during that time period in Taiwan.

and Written Expression and on Reading Comprehension and Vocabulary, however, is probably less a function of linguistic similarities with the English language than of extensive instruction in and through English, usually for three years in primary school and five years in secondary school. The low mean score of the African group on Listening Comprehension perhaps attests to their familiarity and use of different accents and speech patterns than those prevalent in English as spoken in the United States. That the rank-order of language groups varies by section scores lends support to the existence of separate dimensions in English proficiency and to the examination of discrepant item performance by section. The similarities of the means and standard deviations for the dual Chinese samples drawn for each test administration suggest little fluctuation due to sampling within test administrations. The standard deviations of the language groups' section scores reflect sometimes marked differences in the spread of the respective groups' score distributions (see Appendix C).

Correlations of the item difficulty values between groups appear in Table 2 for the first test administration 2 and Table 3 for the second test administration. The means of the item difficulty values reported in these tables restate the groups relative standing on each test section with respect to their mean scores, as given in Table 1. The correlations of item difficulties for the two Chinese samples on each test section, r = .99, show the strength of association between independent samples

²One item from the TOEFL Section on Structure and Written Expression had been omitted from the operational scoring for this test form because of differences between American and British vocabularies. It was also excluded from analyses in this study.

from the same language group. These duplicate samples also have nearly identical correlations with the item difficulties of other language groups. But there is certainly variation in the strength of association between item difficulty values across groups as reflected by these correlations with the Chinese samples, ranging from a low correlation between the Chinese and Spanish groups on Section III in Administration I, r = .43, to a high correlation between the Chinese and Japanese groups on Section III in Administration II, r = .92.

The lower correlations in Tables 2 and 3-indicate a greater relative success on some items and failure on other items for one language group contrasted with another. Groups with disparate mean scores can have similar patterns of item difficulty values, for example, the Germanic-Arabic correlation on Section II in Administration I, r = .89. And groups with comparable mean scores can have dissimilar patterns of item difficulty values, for example, the Japanese-Arabic correlation on Section II in Administration I, r = .59. The lower correlations reflect the degree of dissimilarity in patterns of item difficulties between two groups; high correlations, on the other hand, may reflect consistent differences in item difficulty values across items. Appendix B illustrates relative advantages and disadvantages in item performance through the delta plots corresponding to the correlations for Section III in Administration I, the section with the lowest correlations and the greatest range in correlation values.

While the average correlations of item difficulty values for the TOEFL Sections on Listening Comprehension and on Structure and Written.

Expression remain fairly stable from the first test administration to the second test administration, there is a sizeable change in the average

correlation for the TOEFL Section on Reading Comprehension and Vocabulary (i.e., r = .68 for Administration I and r = .83 for Administration II). Almost every entry in the correlation matrix for Section III in Administration II is higher than the corresponding entry in Administration I (see . Tables 2 and 3). The likelihood that this merely reflects changes in the composition of the samples drawn for the respective language groups from one test administration to another seems low given the greater stability of the average correlations for the other two TOEFL Sections (i.e., r = .83and .78 on Section I, and r = .78 and .81 on Section II). It seems more probable that the change in the average correlation for the TOEFL Section on Reading Comprehension and Vocabulary is attributable to variation in test forms, This finding is especially important because Swinton and Powers (1980) based their exploratory factor analysis of the TOEFL on the same data set from Administration L, the form with lower entries in its correlation matrix of item difficulty values across language groups for the TOEFL Section on Reading Comprehension and Vocabulary, and found evidence suggesting a separate factor for vocabulary. The variation in test forms on the pertinent TOEFL Section observed here suggests that further research on the test's factor structure should be undertaken in order to verify the existence of a separate vocabulary dimension of English proficiency and that particular attention should be given to the test specifications for this section in developing equivalent forms.

Differential Item Performance Across Language Groups

Detecting instances in which the item performance of examinees of comparable ability differed by language groups entailed contrasting the item performance of several language groups at the same score level.

Accordingly, the score distribution of the complete sample of language groups was divided into ten score intervals for each section of the test, with approximately equal numbers of examinees at each score level. It was also required that each language group have at least ten examinees at any particular score stratum as a check for an arbitrary minimum frequency in the marginal distribution of language groups by score strata, $n_{ij+} \ge 10$. These score distributions by language groups appear in Appendix C for each test section and both test administrations.

The Germanic language group so far exceeded the other language groups in their test performance on each TOEFL Section (see Table 1 and Appendix C) that it was not possible to include seven language groups and ten score strata in calculating, chi-square values and still maintain minimum frequencies in the marginal distributions of language groups by score strata. Fewer than one-tenth of the Germanic examinees were in the lower half of the score distribution for the TOEFL Section on Listening Comprehension and fewer than ten Germanic examinees were always in the lowest tenth of the score distributions for the other two TOEFL Sections. Consequently, the Germanic language group was omitted from the chi-square analysis for the TOEFL Section on Listening Comprehension and the ninth and tenth score strata were collapsed together in the chi-square analyses for the TOEFL Sections on Structure and Written Expression and on Reading Comprehension and Vocabulary.

The number of items on which the chi-square analysis resulted in a statistically significant value is given in Table 4. Clearly the proportion of items shown to elicit differential performance across various language groups, nearly seven-eighths of the total number of items, is greater than the proportions identified through statistical indices in other

language groups in the extent of the similarities and dissimilarities of their languages with the English language. That such contrasts played a role in the results was particularly evident with respect to vocabulary: the highest chi-square values were obtained for items from the TOEFL Section on Reading Comprehension and Vocabulary, and these were items requiring examinees to choose a synonym for a given word in a sentence. It is perhaps also attributable, in part, to the number of groups, number of score strata and size of samples employed in the chi-square analysis for this study.

Percentage deviations from expected frequencies of correct item responses begin to explain statistical significance in this context. Table 5 presents chi-square values for the items from the TOEFL Section on Reading Comprehension and Vocabulary in Administration I, the section which had the lowest intercorrelations of item difficulty values between language groups, along with each group's relative advantage or disadvantage on these items, expressed as a percentage deviation from the expected frequency of correct item responses for that particular group and item. (Appendix D gives the total chi-square values, percentage deviations, and item difficulty values for call items.) The extent of these deviations from expected performance tends to follow the magnitude of the chi-square values for the items. A significant chi-square value, however, may result from very modest variations in item performance across groups. Item 45 * had a significant chi-square value, $\chi_{L_{\kappa}}^{2}$ (54) = 92.39 and p < .001, but showed just a seven percent increase in correct responses among Chinese examinees and a six percent decrease among Spanish examinees. Item 14, on the other, hand, had a much higher chi-square value, $\chi^2 = 1408.41$ and p < .001, and a'

much greater range in percentage deviations among groups. Statistical significance by itself can vary widely in its implications for the relative advantages and disadvantages held by different groups on a test item.

Both the chi-square procedure and the calculation of percentage deviations assume that differential item performance by groups holds across ability levels. Otherwise the aggregation across score strata might obscure differences from level to level in item discrimination and distort relative advantages and disadvantages among groups. The second column of chi-square values given in Table 5 reveal the significance of the three-way interaction among item responses, language groups, and score strata for each item. For half of the items this interaction was not statistically-significant, X₂(48) < 73.67 and p > .01, and the likelihood-ratio chi-square values for the interaction even when statistically significant were much smaller than the overall chi-square values. The relative advantages and disadvantages for different language groups reported as percentage deviations from expected frequencies of correct item responses in Table 5 seem to be fairly stable across strata in the score distribution.

The distributions of percentage deviations by language groups appear in Table 6 for the TOEFL Sections in Administration I and in Table 7 for the TOEFL Sections in Administration II. These distributions illustrate the consistency of item performance by language groups, given the item performance of the total sample as a standard for comparison, and the frequency of relative advantages and disadvantages by language groups.

Each distribution necessarily centers near zero because scores on the test sections served as an internal criterion for expected frequencies of correct item responses and, in effect, precluded skewed distributions of percentage

deviations indicating an overall advantage or disadvantage on the test for a particular group. The modal deviation for each distribution is within ten percent of the expected frequency of correct item responses, and the majority of deviations occur within this same range except for the African language group on TOEFL Sections II and III. Large deviations from expected item performance (i.e., over thirty percent greater or fewer correct item responses than expected) are infrequent but occur more often in the TOEFL Section on Reading Comprehension and Vocabulary, perhaps suggesting that knowledge of specific words in the context of single sentences and reading passages is more susceptible to linguistic contrasts than either aural skills or syntactical rules. The extent and spread of percentage deviations within the African group further suggests the heterogeneous nature of this group, which included four different native languages (i.e., Ibo, Yoruba, Efik, and Fanti) more on the basis of their geographical proximity than their linguistic comparability.

Linguistic Explanations for Discrepant Item Performance

By expressing each group's relative advantage or disadvantage on an item, percentage deviations can facilitate examining the possible reasons for discrepant item performance among groups. Item 14 from the TOEFL Section on Vocabulary and Reading Comprehension in Administration I provides a convenient example since it had the highest chi-square value of any item. That item required examinees to choose the response which best kept the meaning of a word in a sentence:

- 14. The card had perforations in the upper left corner.
 - "(A) holes (B) numbers
 - (C) symbols
- (D) lines

Just the percentages of correct responses on this item revealed substantial variation across language groups: 37% and 38% correct for the two Chinese samples; 40% correct for the Japanese sample; 50% correct for the Arabic sample; 90% correct for both the African and Germanic samples; and 99% correct for the Spanish sample. The percentage deviations from expected frequencies of correct responses for the item (see Table 5) showed a somewhat different pattern of relative advantage and disadvantage among the language groups. The Chinese and Japanese examinees indeed had fewer correct responses than expected, -33% and -26%, primarily because these language groups tended to choose the distractor "symbols" which perhaps seemed to fit the content of the item stem. Despite attaining the same proportion of correct responses, African examinees found this item easier than other items in the section, a +40% deviation from their expected item performance, while Germanic examinees found the item only somewhat easier, 1 +12% deviation. The performance and advantage of Spanish examinees on this item undoubtedly stems from cognates for both "holes" and "perforations" in their native language, "hoyo" and "perferacion." Similarly, Germanic examinees probably benefited from the noun "hohle" and the verb "perforieren" in their own language. The performance of Arabic examinees on this item was consistent with their performance on other items in the same test section as reflected by the slight percentage deviation from the expected frequency of correct responses for this language group. Percentage deviations from expected frequencies of correct item responses, unlike simple proportions or percentages of correct item responses; take score account and therefore seem to yield richer information for the interpretation of differential item performance across groups.

Specialists in English as a foreign language reviewed the results of the analyses for Administration II and attempted to mentify probable instances of discrepant item performance given only the test form and answer key for Administration II. The complexity of the reviewers' task became readily apparent. Seven reviewers examined the most extreme cases of differential item performance found in the first test administration and offered possible explanations for the observed differences among language groups. But these explanations necessarily depended on each reviewer's familiarity with the several native languages and the linguistic similarities and dissimilarities with the sound, syntax, semantics, and vocabulary of the English language mually a reviewer was familiar with two or three languages and offered comments about an item based only on the performance of those particular language groups.

The success of the reviewers in identifying instances of discrepant item performance on a second test form demonstrate the difficulty of judgmental approaches to this problem. Six reviewers made informed. guesses, or "shots in the dark" as one specialist described them, about the ten items from each test section which might exhibit the greatest differential performance across language groups and thus result in the highest chi-square values. Asked to identify the ten most discrepant items of the fifty items in the TOEFL Section on Listening Comprehension, the reviewers were correct 12 times in 64 tries. Asked to identify the ten most discrepant items of the forty items in the TOEFL Section on Structure and Written Expression, the reviewers were correct 13 times in 53 tries. Both of these success ratios are simply at the chance level. Asked to identify the ten most discrepant items of the sixty items in the TOEFL

Section on Reading Comprehension and Vocabulary, the reviewers were correct 19 times in 60 tries—a success ratio close to double the chance level but still too unreliable for practical application. One vocabulary item, which ranked third in the order of chi-square values for items within this section, was chosen by all six reviewers: the stem and the correct response on this item were both Spanish cognates and the Spanish language group did show a sizeable relative advantage on the item. Five reviewers also chose another specific vocabulary item; the observed frequencies of correct responses on that item were within ten percent of the expected frequencies for each language group.

A seventh specialist had declined to participate in the second phase of the reviewers' task, noting that a priori contrastive analysis had not proven to be effective in its application, at least to nonphonological areas, and suggesting several references. Contrastive analysis calls for systematic comparisons of the native language and the second language with prescriptions for teaching based on these comparisons. Wardhaugh (1970) noted that such contrastive analysis "makes demands of linguistic theory, and, therefore, of linguists, that they are in no position to meet" (p. 125). An a posterioricanalysis of observed difficulties in second language acquisition may become helpful in teaching and testing, but a priori contrastive analysis reliant on linguistic similarities and differences alone may be just speculation (Schachter & Celce-Murcia, 1977; Wardhaugh, 1970).

Judgmental approaches to identifying items which might exhibit differential performance among language groups depend too heavily on simultaneous a priori contrastive analyses of several different languages with the English language. Detecting instances of differential item

performance by language groups would seem to require the selection and 'application of both an appropriate statistical procedure and a meaningful measure of each group's relative advantage or disadvantage on an item.

SUMMARY AND CONCLUSIONS

A high proportion of TOEFL items, nearly seven-eighths of those.

involved in this study, were found to be sensitive to examinees native,
languages. Examinees from several language groups, despite comparable test,
scores, differed in their performance on specific items according to their
native language. Specialists in English as a second language attributed
such differential item performance to linguistic similarities and dissimilarities with the English language. Yet these same reviewers were unable to
predict which items would exhibit marked discrepancies in performance
across language groups from a test form and answer key alone.

It seems obvious that a native language influences acquisition and performance in a second language. Less clear and perhaps unknown is the degree to which a test of proficiency in a second language accurately reflects linguistic affinity with an examinee's native language. Vocabulary test items, for example, may happen to include cognates of a particular language as both stem and key and thus offer examinees from that language group a distinct advantage. Statistical procedures, now available can isolate instances in which performance on a given item is inconsistent across groups after overall ability has been taken into consideration.

But a significant result from a statistical procedure for detecting discrepant item performance seems to constitute insufficient grounds for rejecting an item in this context. There were cases here in which deviations of less than ten percent from the expected frequencies of correct

item responses across language groups led to a statistically significant index of discrepant performance on an item. In other cases the percentage deviations from expected frequencies of correct item responses seemed to reflect contract with the English language. Still other items, however, may lead to exaggerated or unexplained deviations from the expected item performance across language groups, performance inconsistent with examinees ability and unaccountable by linguistic similarities and dissimilarities. These latter items could distort examinees scores across language groups as well as across test forms.

The statistical procedure for detecting discrepant item performance followed in this study was a chi-square analysis. Unlike other procedures, it lends itself readily to the examination of multiple groups and multiple mensions. Here the concern was comparisons of item performance across several language groups; other studies might focus on individual items and patterns of response choices, including distractors, across groups or expand the number of dimensions so as to investigate differences in item performance by sex or level of education. The chi-square procedure can also provide measures of item discrepancy for each group, such as percentage deviations from expected frequencies of correct item responses, dead naturally to estimates of other effects or interactions through log-linear models. Moreover, this statistical procedure is practical for routine use in developing tests, in that its application is straightforward and efficient. But like other statistical procedures reliant on an internal ability criterion, chi-square analysis is effective in detecting instances of discrepant item performance only insofar as the test score itself represents fair measure of the construct of interest.

TOEFL Research Reports

The Performance of Native Speakers of English on the Test of English as a Foreign Language: Clark, John L.D. Report 1 November 1977.

Discusses the results of the administration of TOEFL to native speakers of English just prior to their graduation from a college-preparatory high school program. Total test score distributions were highly negatively skewed, reinforcing findings of earlier studies that TOEFL is not psychometrically appropriate for discriminating among native speakers of English with respect to English language competence.

An Evaluation of Alternative Item Formats for Testing English as a Foreign Language: Pike, Lewis W. Report 2. June 1979.

Describes an extensive research support includes an extensive research support includes the results of these findings and discusses the implications for TOEFL content specifications were investigated. The report includes the results of these findings and discusses the implications for TOEFL content specifications and internal structure. This study contributed to the restructuring of TOEFL beginning in 1976.

The Performance of Non-Native Speakers of English on TOEFL and Verbal Aptitude Tests: Angelis, Paul J.; Swinton, Spencer S.; and Cowell, William R. Report 3. October 1979.

Gives the results of a study in which 400 graduate and undergraduate applicants took TOEFL and either the GRE Verbal or the SAT Verbal and the Test of Standard Written English (TSWE). Included in the report are comparative data on performance across tests and interpretive information on how combined test results might best be used in the admission process.

An Exploration of Speaking Proficiency Measures in the TOEFL Context: Clark, John L.D., and Swinton, Spencer S. Report 4. October 1979.

Describes a three-year study involving the development and experimental administration of test formats and item types aimed at measuring the English-speaking proficiency of nonnative speakers. Factor analysis and other techniques were used to-identify subsets of item formats and individual items having satisfactory correlations with the Foreign Service Institute criterion interview administered to the test subjects. The results were grouped into a prototype "Test of Spoken English."

The Relationship between Scores on the Graduate Management Admission Test and the Test of English as a Foreign Language; Powers, Donald E. Report 5. December 2000.

Summarizes analyses indicating performance of 6,000 nonnative speakers of English on TOEFL and GMAT. In addition to comparisons between harve and nonnative speakers, data are included showing performance by language background. A variety of analyses support the basic differences in the two tests by showing expected GMAT verbal scores for various levels of TOEFL socres.

The for Analysis of the Test of English as a Foreign Language for Several Language Groups: Powers, Donald E., and Swinton, Spencer S. Report 6. December 1980.

Provides evidence from a set of exploratory analytical techniques that three major factors underlie performance on TOEFL. Some support is also found for concluding that these factors may be interpreted differently for several language groups. The report discusses implications for making inferences based on TOEFL subscores and considerations for future test development.

The Test of Spoken English as a Measure of Communicative Ability in English-Medium Instructional Settings: Clark, John L.D., and Swinton, Spencer S. Report 7. December 1980.

Presents the results of a study that examined the performance of foreign teaching assistants on the Test of Spoken English in relation to their classroom performance as judged by students. Also includes, for purposes of comparison, data showing performance of the same groups of teaching assistants on the Foreign Service oral interview and on TOEFL. Based on the analyses conducted in the study, TSE is shown to be a valid predictor of language abilities for nonnative English-speaking graduate teaching assistants.

Effects of Item Disclosure of OEFL Performance: Hale, Gordon A.; Angelis, Paul J.; and Thibodeau, Lawrence A. Report 6.

Reports the findings of a study designed to examine the effects of performance on TOFFL when a subset of items have been disclosed prior to an administration. Based on data from 16 intensive English training programs, the results indicate significant increases in performance in proportion to the number of items made available to students. Details are provided showing separate results by language group and by item type.

Item Performance Across Native Language Groups on the Test of English as a Foreign Language: Alderman, Donald L., and Holland, Paul W. Report 9. August 1981.

Examines the performance of different native language groups on TOEFL items. Based on the item responses of seven language groups on two test porms, the analyses for test examinees with comparable scores show significant differences in their item performance according to their respective native languages. Specialists in English as a second language analyzed these differences from the point of view of similarities and dissimilarities between the examinees native language and the English language. Discusses implications for the interpretation and examination of item performance by groups.
